Abstract

Despite adjustments to China's fertility policies, the current situation of low new-born population numbers and the public's low fertility intentions have not been effectively improved. Enhancing fertility intentions and improving population structure have become critical issues that need to be addressed urgently. The fertility intentions of new-generation professional women play a significant role in fertility rates. This paper analyzes the main factors affecting fertility intentions from four dimensions: cost-benefit, family resources, career development, and social networks, and thus puts forward countermeasures and suggestions.

In *2024 5th International Conference on Computer Science and Management Technology (ICCSMT 2024), October 18–20, 2024, Xiamen, China.* ACM, New York, NY, USA, 8 pages. https://doi.org/10.1145/3708036.3708049

1 Introduction

In 2021, the state advocated that a couple could have up to three children. However, according to the survey published at the "2023 Annual Meeting of the Chinese Population Association," China's total fertility rate had dropped to 1.09 in 2022, far below the replacement level. Under the relatively relaxed fertility policy background, the fertility rate has not increased but decreased, indicating that non-policy factors have become strong factors affecting fertility intentions. With the development of the economy and society, the proportion of new-generation professional women in the optimal fertility group is increasing, and their fertility intentions directly affect China's total fertility rate and the renewal of the labor force and population structure optimization.

2 Literature Review

2.1 Concept Definition

2.1.1 New-Generation Professional Women. This paper defines new-generation professional women as those born between 1980 and 1999, who share the same social transformation experiences such as globalization, the popularization of the internet, family planning, and other historical events. They have fewer children in their original families and are well-educated women who are engaged in various positions in various enterprises and institutions.

2.1.2 Beijing Central Business District (CBD).. The Beijing CBD is a bustling commercial area with many high-rise buildings, international companies, and high-end shopping centers. It is one of the top commercial areas in Beijing and even in China. It is an important part of Beijing's business center, the financial center, international business center, and modern service industry center of Beijing. It gathers many well-known enterprises and financial institutions at home and abroad.

2.1.3 Fertility Intentions. Fertility intentions are subjective desires reflecting whether people will have children, the number of children, the timing of childbirth, and preferences for the gender of children. It specifically refers to an individual's willingness and expectations to have children, including preferences for the number of children, timing of childbirth, and gender. Fertility intentions are an important part of research in the fields of demography, sociology, and economics because they directly affect a country's fertility rate and population structure, which in turn affect economic development and social stability[1].

2.2 Theoretical Basis

2.2.1 Work-Family Conflict Theory. The work-family conflict theory was first proposed by Kahn and Wolfe (1964), who believed that work-family conflict refers to the conflict between the demands of the work role and the individual's family role, and the individual cannot balance the pressures from both sides. Specifically, when an individual's roles and responsibilities in the work and family fields conflict and the individual cannot effectively balance the pressures of both roles, work-family conflict arises. This conflict can lead to

difficulties in maintaining commitment to work roles while meeting family role requirements, and vice versa.

2.2.2 Parent-Child Information Research. Currently, there is no strict and clear definition of parent-child information in academia. Domestic scholars Huang Junjie and Qiu Ting divide parent-child information into three categories: parenting information, educational information, and parent-child relationships. Parenting information refers to the information provided by parents for their children's life and growth needs; educational information refers to the information that parents or elders have within the family scope, using their own words and deeds to enlighten and educate children, thereby shaping children's thoughts and personalities; parent-child relationships refer to the emotional relationships between parents and children.

2.2.3 Cost-Utility Research. The cost-utility hypothesis theory of childbirth suggests that the costs and benefits of having children determine people's fertility decisions. The cost of childbirth includes direct and indirect costs, such as medical expenses for childbirth, education costs, time costs, etc.; the benefits of childbirth include the spiritual pleasure and kinship satisfaction that children bring to parents, as well as the role of children as labor and economic security[2].

2.3 Research Hypotheses

Based on past domestic and foreign research findings, factors affecting individual fertility intentions can generally be summarized into macro and micro levels. On the macro level, Wei Wei, Yang Xiaofeng, and others have explored the impact of satisfaction with public services and public education on residents' fertility intentions. Xu Kangshun, Fan Junhui, through the exploration of the relationship between pension insurance and fertility intentions, found that the payment of pension insurance would reduce the family's fertility intentions. Duan Jihong, Su Huashan, and others have studied the cost of childbirth and found that the economic and life pressures faced by families, the resistance of the first child, and the contradictions in the distribution of family resources all have an impact on the birth rate of the second child. On the micro level, some scholars have studied women's fertility intentions from the perspective of the conflict between work and family. Cleland and others believe that the use of the internet has impacted the traditional concept of "raising children to prevent old age." Domestic scholars Qiu Lei and Feng Yiqiang, using data from the China Family Panel Studies, have explored the impact of the use of the internet on residents' fertility intentions, and believe that the use of the internet has reduced people's fertility intentions[3].

In summary, domestic and foreign scholars have achieved fruitful results in the study of factors affecting fertility intentions. Based on the above theories, this study on the fertility intentions of new-generation professional women mainly makes the following assumptions:

Hypothesis 1: The cost-utility theory will have an impact on individual fertility intentions;

Hypothesis 2: Work-family conflict will have an impact on individual fertility intentions;

Hypothesis 3: Family resources will have an impact on individual fertility intentions;

Hypothesis 4: Browsing parent-child information on social networks will have an impact on individual fertility intentions; positive parent-child information will increase people's fertility intentions; negative parent-child information will reduce people's fertility intentions.

3 Research Design

3.1 Research Path

First, theoretical research. Clarify the research theme of fertility intentions and define the specific scope of the research subjects.Second, formulate hypotheses. Analyze the factors affecting the fertility intentions of new-generation professional women through theoretical research.Third, determine the plan. This survey selects new-generation professional women in enterprises in Beijing's Central Business District as the research subjects.Fourth, implement the survey. Based on Zheng Zhenzhen (2014) and Wang Jiwen (2018) as the theoretical basis, design the survey questionnaire from the dimensions of ideal number of children, expected number of children, and fertility intention. The survey uses questionnaire surveys and personal interviews to collect data and conduct surveys.Fifth, data processing. Use SPSS for descriptive statistical analysis and logistic regression analysis for data and conclusion analysis to ensure the effectiveness of the data.Sixth, summarize and induce. Analyze and summarize the problems in the data, and then put forward rational suggestions and opinions.

3.2 Analysis Strategy

Qualitative and quantitative analysis strategies are adopted. Word frequency statistics and problem analysis are conducted for the interview text to effectively capture the influencing factors through qualitative analysis. Then, SPSS25.0 software is used for data analysis and processing of the survey questionnaire, and correlation analysis is carried out on relevant factors.Based on the collected data samples, this paper uses SPSS25.0 software for statistical analysis. First, descriptive analysis is conducted on the main variables of the sample. Then, regression analysis is performed on the main variables to explore whether cost-utility economy, social networks, career development, and family resources will have an impact on fertility intentions.In addition, this paper also carries out heterogeneity tests based on factors such as position, age, gender preference for children, and expected number of children.

4 Data Analysis

4.1 Sample Analysis

The formal survey data of this research comes from office enterprises in Beijing's Central Business District. The project was conducted from November 20, 2023, to November 25, 2023, and a total of 302 questionnaires were collected, of which 298 were valid. Based on the research purpose, the data collected from new-generation professional women in Beijing's Central Business District were cleaned, and finally, 230 valid questionnaires that met the inclusion criteria of this study were selected. The basic information of the research subjects is shown in Table 1. The inclusion criteria of this

Table 1: Sample Distribution Characteristics Description (N=230).

Variable	Category	Frequency	Valid Percentage	Cumulative Percentage
Marital Status	Married	180	78.3	78.3
	Unmarried	44	19.1	97.4
	Divorced	6	2.6	100
	Total	230	100	
Year of Birth	Before1980	20	8.7	8.7

	Two or more girls	11	7.1	100
	Total	156	100	

study are: ① Work location is in the Central Business District office; ② Female; ③ Born between 1980 and 1999; ④ Voluntarily fill in the questionnaire to participate in this study; ⑤ Exclude individuals who self-reported mental or neurological diseases in the survey questionnaire.This study includes seven control variables, including marital status, year of birth, education level, position, and years of work. The descriptive statistical analysis of the seven control variables is as follows:

From Table 1, it can be found that: In terms of marital status, there are 180 married people, accounting for 78.3% of all the surveyed people, 44 unmarried people, accounting for 19.1% of all the surveyed people, and 6 divorced people, accounting for 2.6% of all the surveyed people, mainly with a higher proportion of married people; In terms of the year of birth, there are 20 people born before 1980, accounting for 8.7% of all the surveyed people, 109 people born between 1980 and 1989, accounting for 47.4% of all the surveyed people, and 101 people born between 1990 and 1999, accounting for 43.9% of all the surveyed people, with the main birth years distributed between 1980 and 1999; In terms of education level, there are 120 people with a bachelor's degree, accounting for 52.2% of all the surveyed people, followed by 77 people with a master's degree, accounting for 33.5% of all the surveyed people, with the rest being less distributed; In terms of position, there are 121 ordinary employees, accounting for 52.6% of all the surveyed people, followed by 52 middle-level managers, accounting for 22.6%

Table 2: Reliability Analysis Results.

Variable	Cronbach's Alpha	Number of Items
Cost-Utility	0.786	5
Family Resources	0.747	2
Positive Social Media Information	0.928	3
Negative Social Media Information	0.779	3
Career Development	0.763	4

Table 3: KMO Sample Measurement and Bartlett's Sphericity Test of Subscales.

Variable	KMO and Bartlett's Test	Approximate Chi-Square	Degrees of Freedom	Significance
Cost-Utility	0.663	298.432	10	0.000
Family Resources	0.600	36.067	1	0.000
Positive Social Media Information	0.754	553.89	3	0.000
Negative Social Media Information	0.696	189.251	3	0.000
Career Development	0.649	490.247	6	0.000

of all the surveyed people, then 36 grassroots managers, accounting for 15.7% of all the surveyed people, and finally 9 senior managers, accounting for 3.9% of all the surveyed people; In terms of years of work, there are 86 people who have worked for 5 (including) - 10 (not including) years, accounting for 37.4% of all the surveyed people, and 71 people who have worked for 10 (including) - 15 (not including) years, accounting for 30.9% of all the surveyed people, showing a trend of fewer distributions at both ends and more in the middle; In terms of fertility status, there are 74 people who have not yet had children, accounting for 32.2% of all the surveyed people, 112 people who have had one child, accounting for 48.7% of all the surveyed people, 43 people who have had two children, accounting for 18.7% of all the surveyed people, and 1 person who has had three or more children, accounting for 0.4% of all the surveyed people, indicating that nearly half of the surveyed population is a family with one child; In terms of the gender of the children, there are 59 boys, accounting for 37.8% of all the surveyed people, 56 girls, accounting for 35.9% of all the surveyed people, and 25 people who have both genders, accounting for 16% of all the surveyed people, with the rest being less distributed. Through the above analysis, it can be found that the surveyed objects are roughly in line with the actual situation in all aspects, which can support the follow-up empirical research of this paper.

4.2 Reliability and Validity Analysis

4.2.1 Reliability Analysis. This study uses Cronbach's alpha coefficient to test and measure the reliability of the sample. Through Table 2, it is found that the Cronbach's Alpha values of each scale are all greater than 0.7, indicating good reliability for further research.

4.2.2 Validity Analysis. Through Table 3, it is found that the KMO values of the cost-utility, family resources, positive and negative social media information, and career development scales are 0.663, 0.600, 0.754, 0.696, and 0.649, respectively, all greater than 0.6; and Bartlett's spherical test shows that the significance probability of the chi-square statistic is zero, indicating that each scale has good validity.

The overall questionnaire is factor-analyzed, and it is found that the KMO value of the overall questionnaire is 0.791>0.7, indicating that there are more common factors among different variables, and Bartlett's spherical test shows that the significance probability of the chi-square statistic is zero, indicating that it is suitable for factor analysis.

During the factor analysis process of the overall scale, measures such as maximum variance rotation and principal component analysis are used to analyze the scale. In addition, the eigenvalue greater than 1 is used as the benchmark for retaining factors, and finally, 5 factors are obtained. According to the conclusion of the variance explanation table, the 5 factors can explain a total of 68.833% of the variance, indicating that different factors have a high explanatory degree for variables, indicating that this scale has good structural validity.

4.2.3 Variance Analysis. Through one-way ANOVA, this paper explains the differences in key variables such as the ideal number of children, cost-utility, family resources, positive social media information, negative social media information, and career development in marital status. The summary results of SPSS software are as follows. Through Table 4, it is found that the significance of one-way ANOVA tests for the ideal number of children and positive social media information is less than 0.05, indicating that there are significant differences in the ideal number of children and positive social media information in marital status; in terms of specific mean values, the ideal number of children and positive social media information perception of married people are generally higher than that of unmarried and divorced people, and divorced people are higher than unmarried people.

Table 4: Variance Analysis of Marital Status.

Key Variables		N	Mean	F	Significance
Ideal Number of Children	Married	180	2.81	7.847	0.001
	Unmarried	44	2.27		
	Divorced	6	2.50		
Cost-Utility	Married	180	3.69	2.072	0.128
	Unmarried	44	3.41		
	Divorced	6	3.33		
Family Resources	Married	180	3.91	1.119	0.328
	Unmarried	44	3.66		
	Divorced	6	3.83		
Positive Social Media Information	Married	180	2.58	6.889	0.001
	Unmarried	44	1.98		
	Divorced	6	2.00		
Negative Social Media Information	Married	180	3.23	1.489	0.228
	Unmarried	44	3.48		
	Divorced	6	3.67		
Career Development	Married	180	3.71	1.011	0.366
	Unmarried	44	3.89		
	Divorced	6	4.00		

4.3 Variance Analysis of Education Level

Through one-way ANOVA, this paper explains the differences in key variables such as the ideal number of children, cost-utility, family resources, positive social media information, negative social media information, and career development at different education levels. The summary results of SPSS software are as follows. Through Table 5, it is found that the significance of one-way ANOVA for career development is less than 0.05, indicating that there are significant differences in career development at different education levels; in terms of specific mean values, the career development scores of master's students are generally higher than others, but the career development scores of doctoral students and above are generally lower than others.

4.4 Variance Analysis of Fertility Status

Through one-way ANOVA, this paper explains the differences in key variables such as the ideal number of children, cost-utility, family resources, positive social media information, negative social media information, and career development in fertility status. The summary results of SPSS software are as follows. Through Table 6, it is found that the significance of one-way ANOVA for the ideal number of children and positive social media information is less than 0.05, indicating that there are significant differences in the ideal number of children and positive social media information in fertility status; in terms of specific mean values, the ideal number of children and positive social media information scores of those who have had two or three or more children are generally higher than others.

4.5 Variance Analysis of Fertility Intention

Through one-way ANOVA, this paper explains the differences in key variables such as the ideal number of children, cost-utility, family resources, positive social media information, negative social media information, and career development in fertility intention. The summary results of SPSS software are as follows. Through Table 7, it is found that the significance of one-way ANOVA for the ideal number of children, positive social media information, and negative social media information is less than 0.05, indicating that there are significant differences in the ideal number of children, positive social media information, and negative social media information in fertility intention; in terms of specific mean values, those who will definitely have another child have higher scores in the ideal number of children and positive social media information, and the lowest score in negative social media information.

4.6 Regression Analysis

In this paper, marital status, year of birth, education level, and other 7 factors are used as control variables, and cost-utility, family resources, positive social media information, negative social media information, and career development are used as independent variables, and the dependent variable is the ideal number of children (Table 8).

5 Main Conclusions

Through sample analysis, it is found that the new generation of professional women's agreement on expecting 1-3 children accounts for up to 82%, but 81% of them have not decided when to have children and are in a state of hesitation, with no significant difference in the gender of the children. Only families with one child expect the second child to be a girl more. Most people look forward to having children, with no particular preference for gender. Family income is an important factor affecting fertility decisions.81% of the samples believe that the family income of children is an important factor affecting their fertility decisions. The higher the family income, the higher the fertility intention and fertility rate. A higher income level can provide better living conditions and educational

	Haven't decided	31	3.55		
	Might have another	19	3.53		
	Definitely going to have another	15	3.60		

resources, thereby making families more confident and capable of raising more children. In addition, through cross-comparison, it is found that people with higher positions have a higher proportion of expecting 3 or 4 children or more, which also verifies the importance of family income in fertility decisions. Emotional utility is greater than value utility, and fertility intention tends to be emotional.53% of the samples show that the utility of children is more emotional. The reason for choosing to have children is to experience a fulfilling life and the happiness of being a parent or to let the elderly enjoy the joy of family. The value utility of "raising children to prevent old age," increasing family labor, and regenerative resources has weakened.

6 Countermeasures and Suggestions

6.1 Strengthen social media information publicity, guide ideology

Based on the trend of fertility intention being emotional, to improve the fertility intention of new-generation working women, extensive social media information education and publicity activities can be carried out to raise people's awareness and cognition of childbirth and family, advocate family values, emphasize the importance of children to individuals and society, and encourage a positive family concept and sense of responsibility.

Firstly, official media can guide and publicize positively through programs, public service advertisements, TV dramas, and other forms, to improve the family perception and fertility awareness of working women. In addition, family and fertility propaganda short dramas or videos can be placed on various channels, enhancing the sense of identity of working women towards family and childbirth in different scenarios. Moreover, various forms of offline activities can be organized to cultivate a good sense of fertility[4].

6.2 Improve the social security system, enhance fertility confidence

According to the survey statistics, the main factors affecting fertility intention involve the social security system for the upbringing and education of children. Therefore, it is recommended to strengthen the construction of the social security system throughout the process from childbirth to upbringing, including maternity insurance, child medical insurance, educational support, tax deductions, etc., to provide more comprehensive social security and welfare, reduce

Table 8: Regression Analysis Table of Influencing Factors of Ideal Number of Children.

the burden on families, and enhance people's confidence and ability to have children[5]. Especially for Beijing, considering solving the problem of school registration or household registration for families with multiple children, providing educational security, can greatly increase fertility confidence.

6.3 Establish a social cooperation mechanism, enrich childcare resources

Encourage enterprises, social organizations, schools, and other institutions to actively participate in infant care work, forming a childcare mechanism dominated by the government, participated by society, and multiple cooperations, and improve the relevant laws and regulations of infant care, clarify the responsibilities and obligations of all parties, and protect the legal rights and interests of infants[6]. Firstly, start from the grassroots, establish community childcare centers to provide care services for community families and solve the childcare problems of low-income groups. Secondly, encourage kindergartens to extend their services and offer professional services for low-age children such as nursery classes and early classes, providing a variety of childcare options for families with payment ability. In addition, strengthen the management and standardized training of nannies and childcare agencies, provide diversified employment opportunities, and improve the infant care mechanism.

6.4 Optimize leave arrangements, enhance fertility confidence

At the enterprise level, provide more flexible working hours and work arrangements, and encourage enterprises to provide childcare leave and flexible work systems[7]. In addition, at the national system level, increase childcare leave for working women and special holidays such as Children's Day, providing more time for childcare and creating a relatively relaxed fertility environment for women of childbearing age, making women more confident in childbirth.
